

Prostate Markers

SelectMDx™

Who To Biopsy

SelectMDx™ helps identify patients at increased risk for aggressive disease, thereby aiding in the selection of men for prostate biopsy.

Science:

A two mRNA gene reverse transcription PCR assay that measures the urinary mRNA levels of DLX1 and HOXC6 biomarkers to aid in patient selection for prostate biopsy. A logistic regression model combining the two genes mRNA levels with established clinical risk factors is used to estimate the likelihood of detection GS ≥ 7 prostate cancer upon biopsy, in addition to the likelihood of no cancer or GS ≤ 6 disease.

Results:

- Increased risk for GS ≥ 7 prostate cancer
- Very low risk for GS ≥ 7 prostate cancer. 98% NPV for GS ≥ 7 disease and 99% NPV for GS ≥ 8 prostate cancer
