

Prostate Markers Decipher®

Who To Treat-Post Surgery

The Decipher® test is conducted on prostate tissue collected after a prostatectomy (post-surgery) for patients who had adverse pathology or a rising PSA. It is used to help guide post-surgery treatment options including the need and timing of radiation.

Science:

Decipher® is 22 RNA biomarkers across multiple biological pathways including cell cycle progression, immune system modulation and androgen signaling. It is based on the whole transcriptome analysis platform.

Results:

The Decipher® provides the probability of metastasis at 5 years after surgery, and 3 years after a detectable PSA.
